Journal of Biosciences Volume 32, Number 6, September 2007 Age-dependent increase in green autofluorescence of blood erythrocytes

SANJAY KHANDELWAL and RAJIV K SAXENA

As printed in the September 2007 issue, figure 1 of the article is incomplete: the bars in figure 1(C) are missing. The complete figure is shown below.

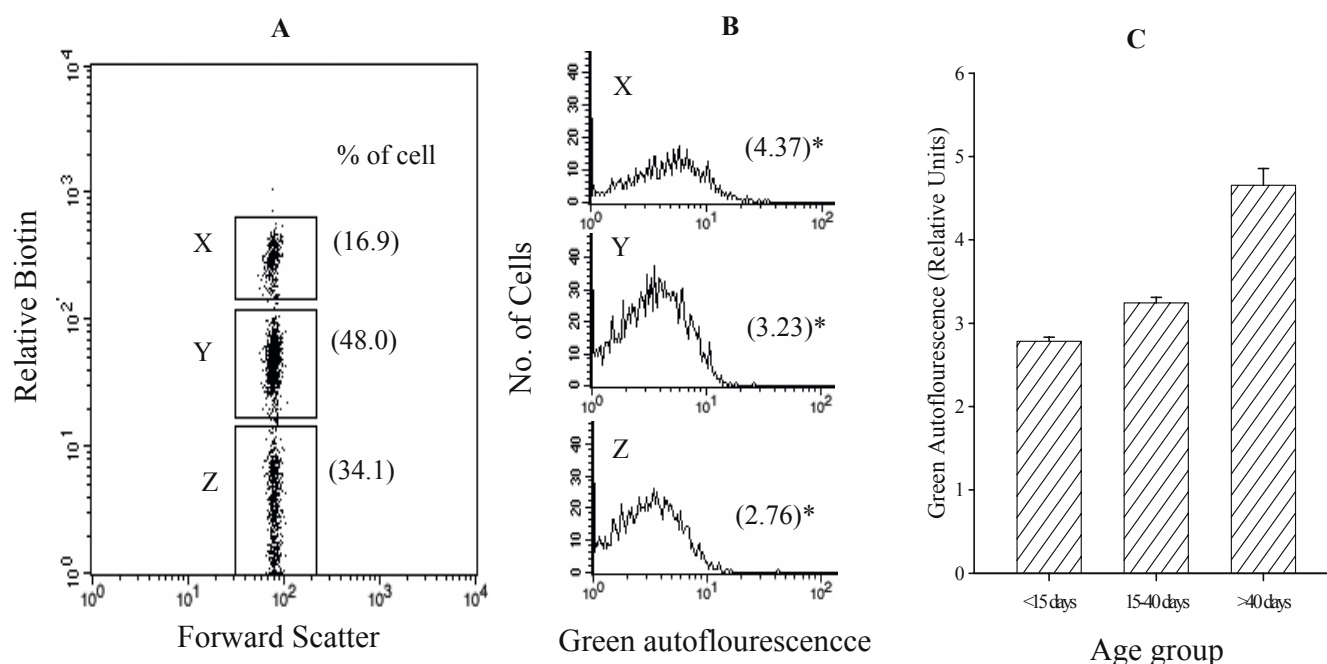

Figure 1. GAF of erythrocytes belonging to young, intermediate and old age groups. Circulating erythrocytes were labelled by DIB technique where the second step of low intensity biotinylation was performed, 25 days after the initial step high intensity biotinylation. After 15 days of the second biotinylation step, erythrocytes were stained with SAV-APC. (A) Demarcation of the three erythrocyte populations i.e. the old (> 40 days of age, box X), intermediate (age 15 to 40 days, box Y) and young (age <15 days, box Z) erythrocytes. (B) Flow cytometric histograms of the GAF emitted by the X, Y and Z boxed populations of erythrocytes. Values in parentheses denote the mean fluorescence intensities (MFIs). (C) Mean and SD of the MFI values obtained from 7 mice. * $P < 0.001$ for difference from youngest age group.
