Abstract. A series of new dicationic dihydrogen complexes of ruthenium of the type $cis\text{-}[(dppm)_2Ru(H^2-H_2)(L)][BF_4]_2$ ($dppm = Ph_2PCH_2PPh_2$; $L =$ phosphite) have been prepared by protonating the precursor hydride complexes $cis\text{-}[(dppm)_2Ru(H)(L)][BF_4]$ using $HBF_4 \cdot Et_2O$. The precursor hydride complexes have been obtained from $trans\text{-}[(dppm)_2Ru(H)(L)][BF_4]$ ($L =$ phosphite) via a rare acid-catalysed isomerization reaction in six coordinate species. The $trans\text{-}[(dppm)_2Ru(H)(L)][BF_4]$ complexes ($L =$ phosphine) upon protonation gave the isomerized derivatives, however, further addition of acid resulted in a five-coordinate species, $[(dppm)_2RuCl]^+$ presumably via an intermediate phosphine dihydrogen complex. The electronic as well as the steric properties of the co-ligands seem to strongly influence the structure-reactivity behaviour of this series of complexes.

Keywords. Hydrogen; hydride ligands; NMR spectroscopy; ruthenium.

1. Introduction

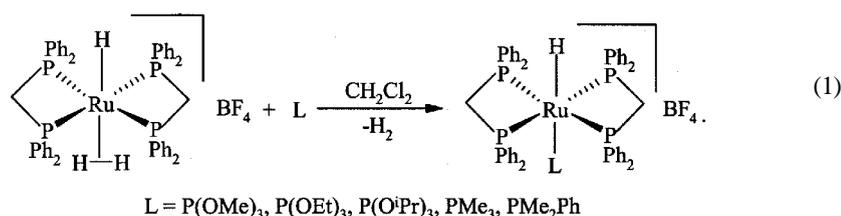

The nature of the ancillary ligand environment in a dihydrogen complex can have a profound effect on the structure and reactivity of the dihydrogen ligand. A thorough understanding of the structure and reactivity of the dihydrogen complexes is required for the rational design of new homogeneous metal catalysts. In this context, transition metal complexes bearing phosphorus co-ligands allows for a very systematic study because both electronic as well as the steric properties of the phosphorus ligands could be varied systematically¹. We have earlier reported the influence of the cone angles and the σ -acceptor properties of certain phosphorus ligands on the structure and reactivity of a series of dihydrogen complexes of ruthenium of the type $trans\text{-}[(dppe)_2Ru(H^2-H_2)(L)][BF_4]_2$ ($dppe = Ph_2PCH_2CH_2PPh_2$; $L =$ phosphite, phosphine)². Morris and co-workers studied the effect of changing the R substituents in chelating phosphine ligands of certain monocationic dihydrogen complexes $trans[(R_2PCH_2CH_2PR_2)_2M(H^2-H_2)(L)]^+$ ^{3,4}. Several others have carried out variations in the cis ligands of dihydrogen complexes $[(L)_4Ru(H^2-H_2)(H)]^+$ to study their influence on the properties of these complexes^{5–10}. In this paper, we wish to focus on the chemistry of dihydrogen complexes of the type $[(dppm)_2Ru(H^2-H_2)(L)][BF_4]_2$ ($dppm = bis\text{-}(diphenylphosphino)methane$, $L =$ phosphite or phosphine). We also compare the present results with the ones obtained earlier⁶ with analogous derivatives consisting of dppe ligands in order to understand the

*For correspondence

effect of the smaller bite angle of the chelating phosphine ligands (here dpmm) on the structure-reactivity behaviour of these complexes.

2. Results and discussion

The substitution of dihydrogen ligand in *trans*-[(dpmm)₂Ru(H)(H₂)] [BF₄] with a monodentate phosphorus ligand, L (L = P(OMe)₃, P(OEt)₃, P(OⁱPr)₃, PMe₃, PMe₂Ph) in CH₂Cl₂ results in *trans*-[(dpmm)₂Ru(H)(L)] [BF₄] complexes,

The new hydride complexes were characterized using NMR spectroscopy and elemental analysis and in one case, *trans*-[(dpmm)₂Ru(H)(P(OMe)₃)] [BF₄] complex by X-ray crystallography.

The hydride complexes *trans*-[(dpmm)₂Ru(H)(L)] [BF₄] (L = P(OMe)₃, P(OEt)₃, P(OⁱPr)₃) were titrated with HBF₄•Et₂O in CD₂Cl₂ under an atmosphere of H₂ and the reactions were studied using NMR spectroscopy. Upon addition of one equivalent of the acid, the *trans* hydride phosphite complexes underwent isomerization resulting in new *cis*-[(dpmm)₂Ru(H)(L)] [BF₄] derivatives (L = P(OMe)₃, P(OEt)₃, P(OⁱPr)₂). The *cis*-disposition of the hydride and the phosphite ligands was ascertained from the ¹H and ³¹P NMR spectral features. The hydride ligand shows a complex multiplet pattern that could be described with a XABCDM spin system in the ¹H NMR spectrum whereas the ³¹P NMR spectrum could be modelled as an ABCDM spin system. In addition, we carried out X-ray crystal structure determination of *cis*-[(dpmm)₂Ru(H)(P(OMe)₃)] [BF₄] complex, which revealed without any ambiguity the *cis*-conformation.

The *cis*-[(dpmm)₂Ru(H)(P(OMe)₃)] [BF₄] complex crystallized from a dichloromethane-petroleum ether solution in space group P-1 with cell dimensions *a* = 9.77640(10) Å, *b* = 15.0833(2) Å, *c* = 20.72300(10) Å, and *a* = 75.75°, *b* = 76.1020(10)°, *g* = 77.1270(10)°. A perspective drawing and the numbering scheme for the cation are shown in figure 1. The structure consists of a severely distorted octahedron: three of the four dpmm phosphorus atoms define a plane whereas, the fourth phosphorus is approximately *trans* to the phosphite ligand that is perpendicular to the plane of the three dpmm phosphorus atoms. The hydride ligand that occupies the sixth coordination site on the metal was not located. The structure could be viewed as a distorted trigonal bipyramid if the hydride ligand is excluded, as shown in the figure. The dpmm bite angles, P(1)-Ru(1)-P(2) and P(3)-Ru(1)-P(4) are respectively, 71.40(7) and 70.89(7)°. The notable feature of the structure is the *tightening* of the Ru(1)-P(5) bond (2.249(2) Å) in comparison to that of the *trans*-isomer (2.3153(17) Å).

A reasonable mechanism of the isomerization could involve the protonation of one of the dpmm phosphorus atoms of *trans*-[(dpmm)₂Ru(H)(L)] [BF₄] complex in the presence of HBF₄•Et₂O. This then allows for the swinging around of the free, protonated end of the dpmm ligand to generate a vacant site *cis* to the hydride. An intramolecular rearrangement

renders the phosphite *cis* to the hydride, followed by the closure of the dppm ring completing the isomerization. The *cis* isomers could be obtained even in the absence of the acid, under refluxing conditions of CHCl_3 solution containing the *trans*-isomers. A *trans* to *cis* product distribution ratio that is dependent on the cone angle of the phosphite ligand was achieved after 20 h under such conditions: greater cone angle of the phosphite results in greater amount of the *cis*-isomer. In the absence of the acid, a different mechanism seems to operate: the phosphite due to its labile nature gets released from the metal centre resulting in a coordinatively unsaturated five-coordinate species. The phosphite then attacks the metal center from a position that is *cis* to the hydride ligand (scheme 1).

The *trans* \rightarrow *cis* isomerization that is promoted by acid as discussed above is a rare example of acid-catalysed isomerization in six-coordinate complexes. Since the isomerization is quite facile, it could mean that a relatively low barrier relates the two isomers.

Upon further addition of $\text{HBF}_4 \cdot \text{Et}_2\text{O}$ to the mixture of the *trans* and the *cis*- $[(\text{dppm})_2\text{Ru}(\text{H})(\text{L})][\text{BF}_4]$ ($\text{L} = \text{P}(\text{OMe})_3$, $\text{P}(\text{OEt})_3$), the respective *trans* and the *cis*-dihydrogen complexes $[(\text{dppm})_2\text{Ru}(\text{H}^2-\text{H}_2)(\text{L})][\text{BF}_4]_2$ were obtained. In the case of the $\text{P}(\text{O}^i\text{Pr})_3$ hydride complex, the addition of one equiv of acid brings about the isomerization of the *trans* to the *cis*-isomer. In addition, a small amount of another

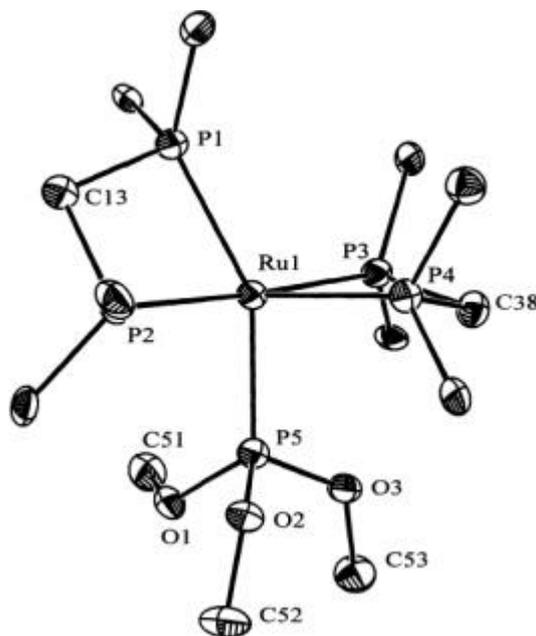

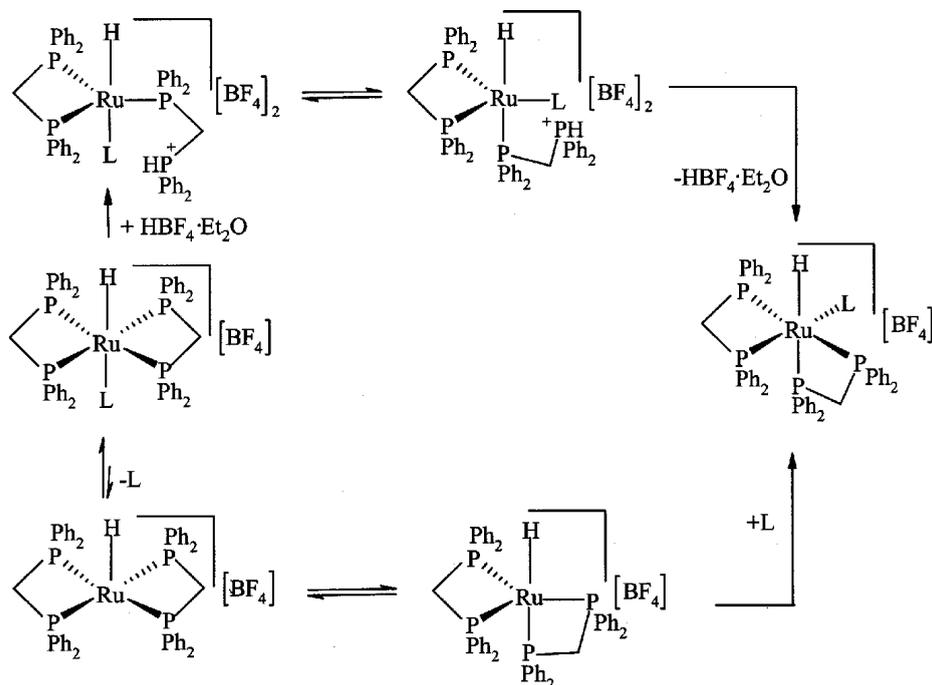

Figure 1. Perspective drawing of *cis*- $[(\text{dppm})_2\text{Ru}(\text{H})(\text{P}(\text{OMe})_3)]^+$ cation. The phenyl groups on the dppm phosphorus atoms have been omitted for clarity; only one carbon atom of each of the phenyl groups is shown in the figure. Selected bond lengths (\AA) and angles ($^\circ$): $\text{Ru}(1)\text{--P}(1)$ 2.379(2), $\text{Ru}(1)\text{--P}(2)$ 2.316(2), $\text{Ru}(1)\text{--P}(3)$ 2.349(2), $\text{Ru}(1)\text{--P}(4)$ 2.417(2), $\text{Ru}(1)\text{--P}(5)$ 2.249(2), $\text{P}(5)\text{--Ru}(1)\text{--P}(1)$ 152.14(8), $\text{P}(5)\text{--Ru}(1)\text{--P}(2)$ 90.20(7), $\text{P}(5)\text{--Ru}(1)\text{--P}(3)$ 93.22(7), $\text{P}(5)\text{--Ru}(1)\text{--P}(4)$ 92.15(7), $\text{P}(2)\text{--Ru}(1)\text{--P}(1)$ 71.40(7), $\text{P}(4)\text{--Ru}(1)\text{--P}(3)$ 70.89(7).

hydride derivative, $trans\text{-}[(dppm)_2Ru(H)(PF(O^iPr)_2)](BF_4)$ was also formed. We reported the mechanism of the formation of an analogous dppe containing species in an earlier report². When further acid was added the respective *cis* and the *trans*-dihydrogen complexes $[(dppm)_2Ru(\mathbf{H}^2\text{-H}_2)(PF(O^iPr)_2)](BF_4)_2$ were obtained. The cone angle reduction (in $PF(O^iPr)_2$) in the otherwise sterically crowded $P(O^iPr)_3$ for the generation of the $trans\text{-}[(dppm)_2Ru(H)(PF(O^iPr)_2)](BF_4)$ that could be observed NMR spectroscopically seems a reasonable prospect. The $cis\text{-}[(dppm)_2Ru(\mathbf{H}^2\text{-H}_2)(L)](BF_4)_2$ complexes are the first examples of dicationic dihydrogen complexes wherein the bound H_2 and a monodentate co-ligand are in *cis*-conformation in the family of compounds of the type $[(diphosphine)_2Ru(\mathbf{H}^2\text{-H}_2)(L)]^{2+}$.

The intact nature of the H–H bond in the dihydrogen complexes was established by the 1H spin-lattice relaxation time measurements, T_1 (400 MHz, 298 K, CD_2Cl_2) and the observation and the measurement of the H, D coupling constant of the \mathbf{H}^2 -HD isotopomers.

On the other hand, the protonation of the hydride complexes $trans\text{-}[(dppm)_2Ru(H)(L)](BF_4)$ ($L = PMe_3, PMe_2Ph$) with 1 equiv of $HBF_4 \cdot Et_2O$ resulted in the complete disappearance of the starting hydride accompanied by the appearance of $trans\text{-}[(dppm)_2Ru(\mathbf{H}^2\text{-H}_2)(H)](BF_4)$ and $trans\text{-}[(dppm)_2Ru(\mathbf{H}^2\text{-H}_2)Cl](BF_4)$ complexes as evidenced in the 1H NMR spectrum. Further addition of the acid led to the disappearance of the hydride dihydrogen complex whereas the dihydrogen chloride complex remained intact. The ^{31}P NMR spectra gave similar indications of the appearance of hydride dihydrogen and dihydrogen chloride followed by the disappearance of the former in the

presence of excess acid. However, when excess acid was added, two new signals were observed that could be assigned to a coordinatively unsaturated species, [(dppm)₂RuCl]⁺.

Most of the catalytic hydrogenation reactions involve dihydrogen complex intermediates which protonate adjacent alkyls in a σ -bond metathesis reaction⁹. The mechanisms of such reactions are poorly understood. In this context, the *cis*-[(dppm)₂Ru(H^2 -H₂)(L)][BF₄]₂ complexes serve as good starting material to study the mechanisms of such reactions as follows: the ligand L *cis* to the dihydrogen moiety in *cis*-[(diphosphine)₂Ru(H^2 -H₂)(L)]ⁿ⁺ could be replaced with alkyls so that the σ -alkyl group could accept H⁺ via a heterolytic cleavage of the bound H₂. Intermediates enroute to the proton transfer could be studied using NMR spectroscopy. Efforts in this direction are underway in our laboratories.
