Abstract. Three pyridine-based Schiff bases namely N²,N⁶-bis(4-methylbenzylidene)pyridine-2,6-diamine (DAP-1), N²,N⁶-dibenzylidenepyridine-2,6-diamine (DAP-2) and N²,N⁶-bis(4-nitrobenzylidene)pyridine-2,6-diamine (DAP-3) were synthesized, characterized, and their corrosion inhibition performance was studied on mild steel (MS) in 1 M hydrochloric acid solution using electrochemical experiments and theoretical study. The results showed that all the three DAPs act as mixed type corrosion inhibitors, and are adsorbed on MS surface by following Langmuir adsorption isotherm. The methyl-substituted DAP-1 showed maximum inhibition efficiency of 98.5% at 40 mgL⁻¹. The formation of inhibitor film on MS surface was confirmed by SEM and AFM. Quantum chemical calculations and Monte Carlo simulations were used to understand metal-inhibitor interaction and orientation of adsorption of DAP molecules. A good correlation was observed between theoretical and experimental results.

Keywords. Schiff base; EIS; AFM; SEM; DFT; Monte Carlo (MC) simulation.

1. Introduction

Mild steel finds wide application in different industries like petroleum refineries, storage tanks, power plants, *etc.*, due to its low cost and high strength. However, it undergoes corrosion in contact with hydrochloric acid, during pickling and de-rusting, industrial cleaning, and acidizing. Therefore, inhibitors are usually added in acid solution to prevent metal dissolution.^{1–3} The corrosion inhibition efficiencies of various organic compounds on the corrosion of steel have been investigated experimentally.^{4–8} The inhibition action of organic compounds related to molecular parameters of inhibitors include the presence of lone pair of electrons pi bonds of aromatic ring, planarity, steric factors, and energy gap between HOMO and LUMO.^{9–15} Schiff bases (SB) are the reaction products of amine and carbonyl compounds and act as a potential class of corrosion inhibitors.¹⁶ These compounds have wide applications in biological, clinical and

industrial fields as corrosion inhibitors, catalysts, dyes, pigments, *etc.*^{17–19}

Survey of the literature reveals that SBs act as efficient corrosion inhibitors for various metals in acidic solution. Negm *et al.*,²⁰ studied the corrosion inhibition behavior of four Schiff bases of the amine as corrosion inhibitors on mild steel in 1 M HCl solution. These authors have reported 60–90% inhibition efficiency (IE) at 400 mgL⁻¹. Sorkhabi *et al.*,²¹ investigated Schiff bases derived from 2-aminopyridine as corrosion inhibitors. These compounds exhibited a maximum IE of 85–95% at 200 mgL⁻¹. Yan Ji *et al.*,²² reported corrosion inhibition action of Schiff base derived from pyridin-2-ylmethyl-N,N-diethylaniline (BPMA) that showed corrosion inhibition efficiency 88.1% at 450 ppm. Hegazy *et al.*,²³ derived Schiff bases from benzylidene thiourea that gave 80–90% inhibition efficiency at very high concentration range (150 mgL⁻¹). The inhibition efficiency of Schiff bases has prompted us to synthesize new Schiff bases to study their corrosion inhibition behavior. In the present investigation, we have synthesized three Schiff

*For correspondence

base derived from 2,6-diaminopyridine, namely, N^2,N^6 -bis(4-methylbenzylidene)pyridine-2,6-diamine (DAP-1), N^2,N^6 -dibenzylidenepyridine-2,6-diamine (DAP-2) and N^2,N^6 -bis(4-nitrobenzylidene)pyridine-2,6-diamine (DAP-3) and studied corrosion inhibition for mild steel corrosion in 1 M HCl medium. The survey of literature showed that these SBs have shown biological activities as anti-cancer, anti-viral, anti-microbial, *etc.*, agents.^{24–26} In addition to this, these molecules are likely to give good inhibition efficiency as they have nitrogen containing pyridine nucleus, two (CH = N) azomethine group and two substituted phenyl groups in the same molecule. These structural features favor adsorption of molecules on the metal surface. The corrosion inhibition tests were performed on mild steel in acidic medium using potentiodynamic polarization, electrochemical impedance spectroscopy, gravimetry, surface SEM by scanning electron microscopy (SEM) and atomic force microscopy (AFM). The theoretical calculations using density functional theory (DFT) and the Monte Carlo simulation were also used to establish a correlation between molecular structures and IE.

2. Experimental

2.1 Materials

The synthesis of Schiff bases is reported in literature²⁷ and the scheme for their synthesis is shown in Figure 1. A mixture of 2,6-diaminopyridine (1.0 mmol) and various substituted aromatic aldehydes were taken in round-bottom flask. 50 mL of ethanol was added to the reaction mixture and refluxed approximately 3–5 h. The obtained solid mass was recrystallized from ethanol. The chemicals used for this synthesis were obtained from Merck and SD Fine, India. The molecular structures, analytical data and abbreviations of the inhibitors are given in Table 1. The NMR spectra of DAPs are given in Supplementary Information (SI) as Figures S1–S3. The mild steel used for the weight loss, surface analysis and electrochemical experiments had the following composition;

(wt%): C = 0.076, Mn = 0.192, P = 0.012, Si = 0.026, Cr = 0.050, Al = 0.023 and remaining Fe. Before performing the experiments, the mild steel specimens were abraded with different grades of emery paper (600, 800 and 1200), washed with the double distilled water, and degreased with the ethyl alcohol. The test solution used for the experiment was prepared by dilution of the analytical grade HCl (37%) with double distilled water.

2.2 Measurements

2.2a Gravimetric Measurements: For gravimetric measurements, the MS specimen was cut into size of $2.5 \times 2 \times 0.025 \text{ cm}^3$. Gravimetric experiments were performed according to ASTM standard method.²⁸ The corrosion rates C_R ($\text{mg cm}^{-2}\text{h}^{-1}$) were calculated using following equation:

$$C_R = \frac{W}{At} \quad (1)$$

Here, W = weight of MS coupon, A = total area and t is the exposure time (3 h). With the calculated corrosion rate, the inhibition efficiency $\eta\%$ was calculated as follows:²⁹

$$\eta\% = \frac{C_R - C_{R(i)}}{C_R} \times 100 \quad (2)$$

The surface coverage (θ) was calculated using the following equation:

$$\theta = \frac{C_R - C_{R(i)}}{C_R} \quad (3)$$

Where, C_R and $C_{R(i)}$ are the corrosion rates in the absence and presence of inhibitor, respectively.

2.2b Electrochemical studies: Electrochemical impedance (EIS) measurements and potentio-dynamic polarization studies were carried out using Echem Analyst (5.50 V) software. All electrochemical experiments were performed in a Gamery three electrodes electrochemical cell with MS as working electrode, platinum as the counter electrode and saturated calomel electrode (SCE) as the reference electrode. The working electrode with the exposed surface of 1.0 cm^2 was immersed into the aggressive solutions with and without inhibitor, and then the open circuit potential was measured

Table 1. Molecular structures and analytical data of DAPs.

Inhibitor	Structure	Analytical data
N2,N6-bis(4-methylbenzylidene)pyridine-2,6-diamine (DAP-1)		$C_{21}H_{19}N_3$, 313.40, 1H NMR (500 MHz, DMSO) 1H NMR (DMSO- d_6): 7.91-8.03 (3 H; CH Pyridine), 7.11-7.56 (m, 10H, CH benzene, 5.27(2H, 2N-CH-C) 2.7-3.2 (6H, CH ₃)
N2,N6-dibenzylidenepyridine-2,6-diamine (DAP-2)		$C_{19}H_{15}N_3$, 285.13, 1H NMR (500 MHz, DMSO) 1H NMR (DMSO- d_6): 7.88-8.16 (m, 3 H; CH Pyridine), 7.11-7.56 (m, 10H, CH benzene, 5.66(2H, 2N-CH-C)
N ² , N ⁶ -bis(4-nitrobenzylidene)pyridine-2,6-diamine (DAP-3)		$C_{19}H_{13}N_5O_4$, 375.10, 1H NMR (500 MHz, DMSO) 1H NMR (DMSO- d_6): 7.87-8.06 (3 H; CH Pyridine), 7.02-7.46 (10H, CH benzene, 5.26(2H, 2N-CH-C)

after 30 min. EIS measurements were performed at corrosion potentials (E_{corr}), over a frequency range of 100 kHz to 10 mHz with an AC signal amplitude perturbation of 10 mV peak to peak. Potentio-dynamic polarization studies were performed with a scan rate of 1 mVs^{-1} in the potential range from -250 mV to $+250 \text{ mV}$. All potentials were recorded with respect to the SCE.

2.2c Surface analysis: The MS coupon was cut into an appropriate dimension of $2.5 \times 2 \times 0.025 \text{ cm}^3$, and then immersed into the 1 M HCl solution in the absence and presence of inhibitors having optimum concentration 40 mgL^{-1} for 3 h. The strip was then taken out and washed with distilled water, degreased with acetone, dried at ambient temperature, and mechanically cut into 1.0 cm^2 size for SEM investigations. SEM study was carried out at an accelerating voltage of 5.0 kV and $5.0 \text{ K} \times$ magnification by using a Zeiss EVO 50 XVP instrument (Germany). AFM study was done using NT-MDT multimode (Russia) controlled by a solver scanning probe microscope controller.

2.2d Quantum chemical calculations: Quantum chemical calculations were performed using density functional theory (DFT) with the Becke's three parameter exchange functional along with the Lee-Yang-Parr non-local correlation functional (B3LYP) with 6-31+G(d,p) basis set using Gaussian 09 program.^{30,31} The theoretical parameters obtained were E_{HOMO} , E_{LUMO} , ΔE ($E_{\text{LUMO}} - E_{\text{HOMO}}$), Mullikan charge on heteroatoms (N, O), and dipole moment (μ). Some other important parameters calculated are: global hardness (η), softness (σ) and the fraction of electron transfer (ΔN) from the metal atom using the following equations, respectively.^{32,33}

$$\Delta E = E_{\text{LUMO}} - E_{\text{HOMO}} \quad (4)$$

$$\eta = \frac{1}{2} (E_{\text{LUMO}} - E_{\text{HOMO}}) \quad (5)$$

$$\sigma = \frac{1}{\eta} \quad (6)$$

$$\Delta N = \frac{\phi - \chi_{\text{inh}}}{2(\eta_{\text{Fe}} + \eta_{\text{inh}})} \quad (7)$$

where, χ_{Fe} and χ_{inh} denote the absolute electronegativity of iron and the inhibitor molecule respectively; η_{Fe} and η_{inh} denote the absolute hardness of iron and the inhibitor molecule respectively. The values of ϕ and η_{Fe} are taken as 4.82 and 0 eV^{-1} .³¹ The local nucleophilic and electrophilic sites were calculated using UCA-FUKUI v 1.0 software³² via Finite Difference (FD) method with the use of the output file from Gaussian 09. The Fukui function (f_k) is the first derivative of the electronic density $\rho(\vec{r})$ with respect to the number of electrons N , in a constant external potential $v(\vec{r})$ and written as follows:^{33,34}

$$f_k = \left(\frac{\partial \rho(\vec{r})}{\partial N} \right)_{v(\vec{r})} \quad (8)$$

Fukui functions favoring electrophilic and nucleophilic attacks can be determined as:³⁵

$$f_k^- = q_k(N) - q_k(N-1) \text{ (For electrophilic attack)} \quad (9)$$

$$f_k^+ = q_k(N+1) - q_k(N) \text{ (For nucleophilic attack)} \quad (10)$$

$$f_k^0 = \frac{q_k(N+1) - q_k(N-1)}{2} \quad (11)$$

Where, k is gross charge of the atom denoted by q_k . The $q_k(N+1)$, $q_k(N)$ and $q_k(N-1)$ are the charges of the anionic, neutral and cationic species, respectively.

2.2e Monte Carlo simulations: Monte Carlo simulations (MC) were performed using Forcite and Adsorption Locator modules in the material studio software 7.0 from BIOVIA- Accelrys (U.S.A.) The simulation was carried out with Fe (110) crystal with a slab of $5 \text{ \AA}$. The Fe (110) plane was enlarged to a (10×10) super cell to provide a large surface for the interaction of the inhibitors. After that, a vacuum slab with $30 \text{ \AA}$ thickness was built above the Fe (110) plane. The condensed-phase optimized molecular potentials for atomistic simulation studies (COMPASS) force field were used to optimize the structures of all components of the system of interest including the corrosion inhibitors. Similar procedure has been documented elsewhere.³⁶⁻³⁹ The MC simulations for the studied inhibitors were carried out in gas and aqueous phase. 100 water molecules were introduced into the simulation box to simulate a realistic aqueous corrosive environment. The simulated annealing procedure adopted in this study uses the Monte Carlo method to determine the adsorption energy of the adsorbate substrate. During the simulated annealing, the adsorbate was heated and then cooled very slowly so that conformational changes will lead to a local minimum being located. The process was repeated several times until very closely related, low energy conformations were obtained.

3. Results and Discussion

3.1 Gravimetric measurement

3.1a Effect of inhibitor concentration: The variation of inhibition efficiency with inhibitor concentrations is shown in Figure 2a. It is observed from the figure that the inhibition efficiency increases as the concentration of inhibitors increases. The obtained results indicate that the corrosion inhibition efficiency of the DAPs is concentration dependent. DAP-1 showed the maximum inhibition efficiency of 98.5% among the three studied inhibitors at the optimum concentration of 40 mgL^{-1} and no change was observed in the inhibition efficiency above this concentration, and thus 40 mgL^{-1} was chosen as optimum. The superior performance of DAP-1 is attributed to the presence of electron donating methyl group and the low inhibition efficiency of DAP-3 is due to the presence of electron withdrawing NO_2 group. Functional groups play an important role in the inhibition efficiency.⁴⁰ The increase in inhibition efficiency is

Figure 2. (a) Variation of the inhibition efficiency ($\eta\%$) with inhibitor concentration at 308 K; (b) Variation of inhibition efficiency ($\eta\%$) with solution temperature (308–338 K) at optimum concentration of inhibitor DAPs; (c) Arrhenius plots of the corrosion rate (C_R) of MS in 1 M HCl in the absence and presence of optimum concentration of DAPs; (d) Langmuir isotherm plot for adsorption of DAPs on MS surface in 1 M HCl.

attributed to an increase in the extent of surface coverage by the inhibitor molecules on the metal surface.⁴⁰

3.1b Effect of temperature: The variation in inhibition efficiency with temperature (308–338 K) is shown in Figure 2b. From Figure 2b, it is seen that inhibition efficiency of the DAPs decrease with an increase in temperature. The decrease in inhibition efficiency is due to the partial desorption of inhibitors molecule from the metal surface.⁴¹ The temperature dependence of corrosion rate (CR) was estimated using Arrhenius equation (Table 2).

$$\log C_R = \frac{-E_a}{2.303RT} + \lambda \quad (12)$$

$$C_R = \frac{RT}{Nh} \exp\left(\frac{\Delta S^*}{R}\right) \exp\left(-\frac{\Delta H^*}{RT}\right) \quad (13)$$

Where, E_a is the activation energy of the corrosion process, R is the gas constant, and λ is the Arrhenius pre-exponential factor; N is the Avogadro number, h is the Planck's constant, R is the gas constant, T is the absolute temperature, ΔS^* is the entropy of activation and ΔH^* denotes the enthalpy of activation. The values of ΔS^*

and ΔH^* were calculated from the plot of $\log C_R/T$ vs $1/T$ (with a slope of $\Delta H^*/2.303R$ and an intercept of $[\log(R/Nh) + (\Delta S^*/2.303R)]$ is a straight line in both in the absence the presence of inhibitor. The values of ΔH^* and ΔS^* are given in Table 3. Positive sign of ΔH^* reflected the endothermic nature of mild steel dissolution process, which suggested the slow dissolution of mild steel.⁴¹ The positive ΔS^* means that an increase in disorder takes place in going from reactants to the activated complex on the metal/solution interface,⁴⁰ which is the driving force for the adsorption process.

The activation energy (E_a) values were calculated by plotting a graph between $\log C_R$ vs $1/T$ at an optimum concentration of inhibitors and are shown Figure 2c. The calculated values of E_a in the absence and presence of inhibitor molecules are shown in Table 3 (Thermodynamic parameters for the adsorption of the inhibitor on mild steel in 1 M HCl at the optimum concentration (40 mgL⁻¹) DAPs). On inspection of Table 3, the value of activation energy is higher in the presence of inhibitors than in the absence because of the increase in the physical energy barrier associated with the corrosion reaction. The higher activation energy and a decrease in

DAP-3	1.3	38.67	91.17	73.35	8.63

the corrosion rate might be due to the formation of a protective film of inhibitors on the metal surface.⁴⁰ Table 3 shows that in the presence of DAPs, E_a and ΔH^* values change in a similar manner, which verifies the known thermodynamic relationship between E_a and ΔH^* .

$$\Delta H^* = E_a - RT \quad (14)$$

The ΔS^* values (shown in Table 3) for uninhibited are large and negative and for the inhibited DAPs molecules it is large and positive. This variation is observed due to the disordering and ordering of the DAPs molecules on the mild steel surface. The higher value for the ΔS^* in the presence of inhibitors than in the absence of inhibitors is due to the adsorption of DAP molecules solution which may be due to the quasi-substitution process between the DAP molecules and the water molecules on the mild steel surface,^{42–44} by which the adsorption of DAPs molecule and desorption of water molecules from the mild steel surface take place.

3.1c Adsorption isotherm: In order to understand the behavior of DAPs on mild steel in 1 M HCl, various adsorption isotherms, namely, Langmuir, Temkin and

Frumkin were tested. Langmuir adsorption isotherm provided the best fit among the studied isotherms. It is represented by the following equation⁴⁵

$$\frac{C_{inh}}{\theta} = \frac{1}{K_{ads}} + C_{inh} \quad (15)$$

Where, K_{ads} is the adsorption equilibrium constant process, C is the concentration of the inhibitor and θ is surface coverage value. A straight line was observed by plotting a graph between $\log(C_{inh}/\theta)$ vs. C_{inh} as shown in Figure 2d, which suggested the adsorption of inhibitor molecules on the metal surface obeys Langmuir isotherm.

The values of K_{ads} in association with the standard Gibbs free energy of adsorption $\Delta G_{(ads)}^{\circ}$ was obtained from the Langmuir adsorption isotherm by the following equation.⁴⁶

$$K_{ads} = \frac{1}{C_{(sol.)}} \exp\left(\frac{\Delta G_{ads}^{\circ}}{RT}\right) \quad (16)$$

Where, R is universal gas constant, T is the absolute temperature and C is the concentration of water (1000 g/L). The values of K_{ads} are represented here in

g^{-1}L . Thus, in this equation, the concentration of water is taken in g/L (1000 g/L) in the place of 55.5 mole/L . The values of K_{ads} and $\Delta G_{\text{(ads)}}^0$ are reported in Table 3. The calculated values of K_{ads} and ΔG_{ads}^0 are given in Table 3. Generally, a higher value of K_{ads} is associated with strong adsorption and higher inhibition. In our present study, the value of K_{ads} obeys the order: DAP-1 > DAP-2 > DAP-3 which is in accordance with the order of inhibition efficiency. From the literature, it is noted that if the value of ΔG_{ads}^0 is around -20 kJmol^{-1} , the adsorption may be due to the electrostatic interactions (physisorptions) and if the ΔG_{ads}^0 is around the -40 kJmol^{-1} then the adsorption is chemisorption. The value of $\Delta G_{\text{(ads)}}^0$ for the present study varies from -38.17 to $-40.16 \text{ kJ mol}^{-1}$, suggesting that the adsorption of inhibitors on the mild steel surface is by mixed mode.^{47,48}

3.2 Electrochemical impedance spectroscopy

The Nyquist plots obtained for mild steel in 1 M HCl with and without the optimum concentration (40 mgL^{-1}) of the inhibitors are shown in Figure 3a. The Nyquist plots are slightly depressed semi-circular curves. This feature might be due to different factors like surface roughness, discontinuity in the electrodes, impurities and the inhibitors adsorption on the electrode surface. The shapes of uninhibited and inhibited mild steel in 1 M HCl are same which suggests that DAPs reduce corrosion without changing the mechanism of corrosion.^{49–51} Figure 3a shows that the addition of DAPs increases the diameter of the semicircle which signifies that the corrosion is controlled by the charge transfer process and inhibition is attributed to the formation of a protective film on the mild steel surface. The fitted Nyquist plots of DAPs are shown in Figure 3(c–e).

The electrochemical impedance parameters such as, polarization resistance (R_p), solution resistance (R_s), magnitude of CPE (Y_o) and heterogeneity (n) were calculated by fitting the impedance spectra to the equivalent circuit model shown in Figure 3b and are tabulated in Table 4 (Electrochemical impedance parameters ($\pm$ SD) for mild steel in 1 M HCl in the absence and presence of optimum concentration (40 mg L^{-1}) of DAPs at 308K). The circuit is a parallel combination of R_p and the constant phase element (CPE) of a double layer. The percentage inhibition efficiency ($\eta\%$) by using R_p is expressed as,⁵⁰

$$\eta\% = \left(\frac{R_{p(i)} - R_p}{R_{p(i)}} \right) \times 100 \quad (17)$$

where, R_p represents the polarization resistance in the presence and the absence of the DAPs at optimum concentration, which is the sum of R_{ct} and R_f . Here, R_f is the film resistance. The data in Table 4 show that R_p increases with the increasing inhibitor concentration, which indicates the enhancement of surface resistance by the inhibitor molecules and the increasing inhibition of mild steel corrosion.⁵² However, the CPE values decrease with the increase in inhibitor concentration due to adsorption of inhibitor molecules on the metal surface.^{52,53} The increase in the R_p value for the inhibited system is due to the formation of the protective film on the metal/solution interface.⁵³ The value of C_{dl} decreases with increasing concentration of DAPs due to the decrease in local dielectric constant or an increase in the electrical double layer thickness at the metal surface.⁵⁴ The imperfect semicircle of the Nyquist plots has been related to the deviation of n from unity (surface inhomogeneity); that is, the pure capacitive behavior could not be achieved due to surface inhomogeneity caused by interfacial and structural origin. The double layer is usually considered as a constant phase element (CPE) rather than a pure capacitor. The CPE is placed for the capacitor to fit the semicircle more accurately and expressed as:

$$Z_{\text{CPE}} = Y_o^{-1} (j\omega)^{-n} \quad (18)$$

Where, Z_{CPE} is the impedance of CPE, Y_o is the CPE coefficient (admittance or reciprocal of impedance) and ω is the angular frequency given by $\omega = 2\pi f$ (having units in rad sec^{-1}). According to the above equation, the phase angle of the CPE impedance becomes independent of frequency having a value of $(-n\pi/2)$ degrees. Hence, the CPE is called the “constant phase element”. The numerical value of n is given by the slope of the linear region of the Bode plot. When the value of n reaches unity, the equation becomes,

$$\frac{1}{Z_{\text{CPE}}} = Y_o j\omega = j\omega C \quad (19)$$

Thus, the CPE behaves as a capacitor when n is close to 1.^{55,56} The double layer capacitance (C_{dl}) can be evaluated as follows:

$$C_{\text{dl}} = \frac{Y_o \omega^{n-1}}{\sin(n(\pi/2))} \quad (20)$$

Where, ω is given by $\omega_{\text{max}} = 2\pi f_{\text{max}}$ at which the imaginary part of the impedance ($-Z_{\text{im}}$) is maximum and other symbols are as defined above. Moreover, the value of n can also be used to represent the nature of CPE, such that CPE characterizes a resistance when $n = 0$ ($Y_o = R$); capacitance when $n = 1$ ($Y_o = C$); inductance when $n = -1$ ($Y_o = 1/L$); or Warburg

Figure 3. Figure 3. continued

impedance when $n = 0.5$ ($Y_0 = W$). The values of the EIS parameters obtained after the spectra fitting are listed in Table 4. The results in Table 4 show that n varies from 0.799 to 0.816 in the presence of the inhibitors, which is comparatively higher than that of the blank,

suggesting that surface heterogeneity decreases in the presence of inhibitors due to formation of protective film on the steel surface.

Bode plots are shown in Figure 3f. It is seen that Bode plots involve only one phase maximum revealing

Table 4. Electrochemical impedance parameters ($\pm$ SD) for mild steel in 1 M HCl in the absence and presence of optimum concentration (40 mg L^{-1}) of DAPs at 308K.

$C_{\text{inh}}(\text{mgL}^{-1})$	$R_s(\Omega)$	$R_p(\Omega\text{cm}^2)$	n	$Y_0(\mu\text{Fcm}^{-2})$	$C_{\text{dl}}(\mu\text{Fcm}^{-2})$	$\eta(\%)$
Blank	1.02(0.02)	7.44 (0.05)	0.798	481.2	137.9	—
DAP-1	0.658(0.02)	433.3(0.03)	0.816	120.7	52.35	98.05
DAP-2	0.567(0.02)	217.7 (0.05)	0.805	125.7	75.04	96.10
DAP-3	0.786(0.02)	157.0 (0.03)	0.799	174.8	104.9	94.58

that corrosion process takes place in one step, which corresponds to one time constant.⁵⁷ It is also seen that from Figure 3f that phase angle value is less than -90° , which signified the non-ideal behavior of capacitor. The more negative value of phase angle and the high value of absolute impedance in the presence of DAPs indicate the superior performance of DAPs.^{58,59} The fitted Bode plots of DAPs are shown in the Figures 3(g–i).

3.3 Potentiodynamic polarizations study

The potentiodynamic polarisation plots (PDP) for MS in 1 M HCl in the absence and presence of DAPs at the optimum concentration of 40 mgL^{-1} are shown in Figure 4. The calculated PDP parameters such as corrosion current density (i_{corr}), corrosion potential (E_{corr}), anodic Tafel slope (β_a), cathodic Tafel slope (β_c) and the inhibition efficiency ($\eta\%$) are given in Table 5. The $\eta\%$ was calculated using the following equation:

$$\eta\% = \frac{i_{\text{corr}} - i_{\text{corr(inh)}}}{i_{\text{corr}}} \times 100 \quad (21)$$

where, i_{corr} and $i_{\text{corr(i)}}$ are the uninhibited and inhibited corrosion current densities, respectively. Figure 4 clearly shows that the addition of DAPs causes reduction of i_{corr} without causing a significant change in E_{corr} , thereby suggesting that all DAPs are good corrosion inhibitors and act as mixed inhibitors.⁵⁸ The parallel cathodic Tafel lines (Figure 4) suggest that the addition of inhibitors does not modify the mechanism of corrosion reaction.⁴¹ On addition of the DAPs, the values for both anodic and cathodic Tafel slopes (β_a , β_c) slightly change, which indicates that the addition of the inhibitor reduces the anodic dissolution of mild steel as well as retards the cathodic hydrogen evolution reaction, without affecting the reaction mechanism.⁶⁰

3.4 Surface analysis

For the surface characterization, scanning electron microscopy (SEM) and atomic force microscopy (AFM) have become most powerful tools for analyzing the of

Figure 4. Polarization curves for corrosion of mild steel in the absence and presence of optimum concentrations of inhibitors.

surface of corroded specimens. From the SEM, the morphology of the metal surface and the accumulation of the corrosion products on the metal can be examined. Figures 5(a–d) (SEM image of mild steel, (a) Blank, (b) DAP-1, (c) DAP-2, and (d) DAP-3), respectively, show the SEM image of uninhibited and inhibited mild steel samples in 1 M HCl for 24 h of the immersion period at the optimum concentration (40 mgL^{-1}) of the inhibitors. The surface of the uninhibited mild steel specimen is highly corroded due to acid attack but in the presence of the inhibitors, the surface is relatively smooth.

The AFM analysis was performed on steel surface after the immersion of samples in acid solutions up to 24 h. The micrographs of the mild steel samples in the absence and the presence of the inhibitors at the optimum concentration (40 mgL^{-1}) are shown in Figure 6(a–d) (AFM image of mild steel, (a) Blank, (b) DAP-1, (c) DAP-2, and (d) DAP-3, respectively). The micrograph of the mild steel surface in the absence of inhibitor is $400 \mu\text{m}$ and in the presence of inhibitors, there is a significant improvement in the smoothness due to the adsorption of the inhibitors on the

metal surface. The calculated average roughness for DAP-1, DAP-2 and DAP-3 are 0.6, 5.2 and $10.0 \mu\text{m}$, respectively.

3.5 Quantum chemical calculations

3.5a Quantum chemical calculations of neutral inhibitor molecules: Frontier molecular orbitals: For understanding the donor-acceptor relationship between the frontier molecular orbital's (FMOs) of the inhibitor

molecules and the metallic surface, HOMO and LUMO were studied. Figure 7 shows the optimized structures, HOMO/LUMO, and ESP of the corresponding corrosion inhibitors. The Mullikan charges are given in the Table 6. Generally HOMO and LUMO represent the electron donating and electron accepting capacity of the molecules.⁶¹ Molecules with higher value of E_{HOMO} (less negative) and lower value of E_{LUMO} (more negative) show greater donor and acceptor tendency with appropriate metal d-orbital, respectively.^{62–64}

Figure 6. AFM images for, (a) Blank, (b) DAP-1, (c) DAP-2, and (d) DAP-3.

It can be seen that in the case of neutral inhibitor molecules (DAP-1, DAP-2 and DAP-3), the HOMO electrons are spread over the phenyl ring and nitrogen atoms of the diaminopyridine ring. In the LUMO regions for DAP-1, DAP-2, the electron density resides all over the ring and in the case of DAP-3, the electron density is spread over the phenyl ring, nitrogen atoms of the diaminopyridine ring and over the nitro group.

Frontier molecular orbital energies: The calculated quantum parameters like E_{HOMO} , E_{LUMO} , ΔE ($E_{\text{LUMO}} - E_{\text{HOMO}}$) are listed in Table 7. The difference in energy level ΔE is an important factor and considered in the evaluation of inhibition potential. Generally, higher value of E_{HOMO} suggests better donor performance of the inhibitor molecules. Table 7 reveals that the value of E_{HOMO} for DAP-1 is larger than that of DAP-2 and DAP-3, which supports the order of inhibition efficiencies obtained experimentally. The highest E_{HOMO} value for DAP-1 is due to the presence of electron donating CH_3 group attached to phenyl ring while lowest E_{HOMO} is attributed to electron withdrawing NO_2 group. Furthermore, the lowest value of E_{LUMO} suggests that DAP-1 has greater electron accepting capacity than DAP-2 and DAP-3.

Softness is also an important parameter, which elucidates the adsorption ability of the inhibitor molecules. Higher value of softness and lower value of hardness (η) is associated with the strong interaction with metal and the high inhibition efficiency. Table 7 shows that the softness of DAP-1 (1.061) is more than that of DAP-2 (0.970) and DAP-3 (0.869), and the hardness order is as follows: DAP-3 > DAP-2 > DAP-1, which is in accordance with the experimentally obtained inhibition efficiency. The values of fraction of electrons transferred (ΔN) are presented in Table 7. It is reported⁷⁰ that electron transfer from an inhibitor to metal takes place easily when the ΔN value is greater than 0 and less than 3.6. Table 8 reveals that for all the neutral molecules the calculated ΔN values are positive and less than 3.6, which suggests that the inhibitor molecules have strong tendency to donate electron to the vacant d-orbital of metal.

Fukui index analysis: The Fukui indices f_k^+ and f_k^- predict the most probable atomic sites of the electrophilic and the nucleophilic activities of the inhibitor molecules.³⁵ Higher value of f_k^+ suggests acceptance of electron from the metal, while higher value of f_k^- sites suggests more interaction with the electron deficient species. The calculated Fukui indices are presented in Table 8. In the case of DAP-1, the most

O28	-	-	-	-	-0.0094	-0.0001

C(1), C(5), N(8), C(9), C(10), C(12), C(15), C(16), C(17), C(19), C(21) and C(23) atoms while, the favorable sites for nucleophilic attack are C(1), C(2), C(4), C(5), C(10), C(14), C(20) and N(8) atoms. Likewise, for DAP-3, the sites for electron acceptance are N(3), N(8), C(10), C(12), C(14), C(16), C(1), C(23) and N(23) atoms whereas, C(1), C(2), N(7), N(8), C(9), and C(20), O(26), O(27), O(28) are the electron donating atoms.

The analysis of Fukui indices reveals that 2,6-diaminopyridine ring along with the phenyl ring are the reactive sites are more responsible for donor-acceptor interactions and thus facilitate the adsorption of inhibitors over the metallic surface. The atomic positions DAPs are given in the Supplementary Information: Tables S1–S3 for DAP-1 (Neutral, Cation, Anion), Tables S4–S6 for DAP-2 (Neutral, Cation, Anion) and Tables S7–S9 for DAP-3 (Neutral, Cation, Anion).

3.5b Quantum chemical calculations of protonated inhibitor molecules: The optimized structures, HOMO and LUMO distributions are shown in Figure 8. The

heteroatom having the most negative value of Mullikan charge is likely to undergo protonation easily. From the inspection of Table 8, it can be observed that the energy gap between E_{HOMO} and E_{LUMO} is less as compared to the neutral molecules after the protonation. Table 8 reveals that all the calculated ΔN values are negative, which means that the electron donation from inhibitor molecules to the metal surface is not possible. It is also noted that E_{LUMO} values of protonated inhibitors shift towards more negative side as compared to the neutral molecules, which suggests that the protonated inhibitors have higher electron accepting capability compared to the neutral molecules. Thus, in protonated molecules the bond formation between inhibitor and metal takes place by the acceptance of electrons by inhibitor molecules from the metal surface.

3.5c Molecular electrostatic potential: The color region for the electrophilic and the nucleophilic attack to know the reactivity of the inhibitors molecule are studied using molecular electrostatic potential (MEP).⁶⁵ The

Protonated	Optimized structure	HOMO	LUMO	ΔE (eV)	Electrostatic potential map
DAP-1				0.6065
DAP-2				1.1160
DAP-3				1.1404

Figure 8. Optimized structure, Frontier molecular orbitals and ESP maps for protonated inhibitors molecules. (a) DAP-1; (b) DAP-2; (c) DAP-3.

MEP map of the inhibitors molecule is calculated by the B3LYP/6-31G(d, p) for the neutral and the protonated inhibitors molecules and are shown in the Figures 7 and 8, respectively. In the MEP map, the color regions lie in the order of red, green and blue. The color region from red to green is for the nucleophilic attack, and the color region from green to blue is for the electrophilic attack. For the neutral molecules, the color region of MEP lies in between red and green, which are more susceptible to the electrophilic attack. In the MEP map of neutral inhibitors, the most negative potential (red color) are around the N3, N7 and N8 atoms of the diaminopyridine ring. The MEP map for DAP-3 has larger color range due to the NO_2 group attached on both sides than the other two inhibitors. From the MEP map of protonated DAP-1, DAP-2 and DAP-3, it can be observed that the whole molecule is ready for nucleophilic attack. The nitrogen atoms (N3, N7 and N8) of the diaminopyridine ring are having the most positive potential (blue color). But in the case of DAP-3, it has both nucleophilic and electrophilic regions due to NO_2 groups on both sides of the ring. The color range for the protonated species is larger than that of the neutral species, which is in accordance with the experimental results.

3.6 Monte Carlo simulations

The interaction between the inhibitor molecule and metal surface was studied by Monte Carlo simulations.⁶⁶

The adsorption behavior of inhibitor molecules over the metal surface is shown in Figure 9. It is clearly seen that the orientation of the studied inhibitor molecule lies flat on the metal surface. The corresponding values for the outputs and descriptors are listed in Table 9. The parameters include the total energy of the substrate–adsorbate configuration, which is defined as the sum of the energies of the adsorbate components, the rigid adsorption energy, and the deformation energy. The substrate energy (i.e., Fe (110) surface) is taken as zero. Moreover, adsorption energy reports the energy released (or required) when the relaxed adsorbate component was adsorbed on the substrate. The adsorption energy is defined as the sum of the rigid adsorption energy and the deformation energy for the adsorbate component. The rigid adsorption energy reports the energy released (or required) when the unrelaxed adsorbate component (before the geometry optimization step) was adsorbed on the substrate. The deformation energy reports the energy released when the adsorbed adsorbate component was relaxed on the substrate surface. Finally, (dEad/dNi) reports the energy of substrate–adsorbate configurations where one of the adsorbate components has been removed.

The large negative value for adsorption energies in Table 9 suggest that the inhibitor molecule strongly adsorbs onto the Fe (110) surface.^{67–69} The maximum negative value of adsorption energy for DAP-1 (−2530.79 kJ/mol) suggest that DAP-1 more strongly

Figure 9. Side views and top views of the most stable configurations for adsorption of, (a) DAP-1, (b) DAP-2, and (c) DAP-3 on Fe (110) surface calculated using Monte Carlo simulations in the gas phase and aqueous phase.

Table 9. Interaction energies between the inhibitors and Fe (110) surface (kJ/mol)

Inhibitors	(Total energy) kJ/mol	Adsorption Energy kJ/mol	Rigid adsorption Energy	Deformation energy	dEad/dNi: Inhibitor'	dEad/dNi : H ₂ O
(gas phase)						
DAP -1	-1030.8	-2530.79	-794.13	-1744.30	-2530.79	-
DAP-2	-860.78	-808.20	-786.48	0.7238	-808.20	-
DAP-3	-767.88	-691.93	-692.66	-14.07	-691.39	-
(aqueous phase)						
DAP -1	-6325.20	-6082.86	-6324.36	241.50	-846.42	-24.01
DAP-2	-5921.07	-5745.38	-5988.39	243.00	-755.50	-28.91
DAP-3	-5965.29	-5989.77	-6249.34	259.53	-929.14	-44.22

adsorbs on the metal surface than DAP-2 and DAP-3 (-808.206, -691.397 in kJ/mol, respectively). This follows the order of the inhibition efficiency obtained in the experiments. The order of the rigid adsorption energy is also according to the experimental results which are as follows: -794.1315, -786.4832, 692.6653 kJ/mol for DAP-1, DAP-2, DAP-3, respectively. In order to get the real corrosive environment, it is necessary to

conduct the MC simulation in the presence of water. Figure 9 shows the inhibitor (DAP-1, DAP-2, DAP-3) configuration in the aqueous phase. Table 9 reveals the adsorption energy values in the aqueous phase for the studied inhibitors, DAP-1, DAP-2 and DAP-3. It is generally noticed that the metal-inhibitor interaction is depicted by the adsorption mechanism. High negative adsorption energy values indicate the more stable and

stronger adsorption. On inspection of Table 9, we see that all the calculated values like total energies, adsorption energies, rigid adsorption energies and deformation energies are very high in the aqueous phase than in the gas phase. This proves that the inhibitor is stable in the aqueous phase and strongly binds to the metal surface. However, there is a change in the regular trends in the Total Energy value, Adsorption Energy value, Rigid adsorption Energy value, and the (dE_{ad}/dNi) Inhibitor value of DAP-2 and DAP-3, in the aqueous phase. It does not follow the experimental result. DAP-3 shows higher energies than DAP-2; this is because of the presence of excess oxygen atoms in the NO₂ group which can bond strongly with water in a hydrogen bonding. (O—H). This increases the interaction of the inhibitor molecule with Fe surface. In the gas phase, such hydrogen bonding interaction is not present, therefore the adsorption of DAP-2 is greater than DAP-3. This shows that in aqueous phase, apart from adsorption of the inhibitor on the metal surface, many processes such as hydrogen bonding, protonation of inhibitor molecules in acid solution, pH of the solution, *etc.*, can lead to a discrepancy in simulation results. From the Table 9, (dE_{ad}/dNi) energy of water from the metal surface gives the information about the ease of water removal from the metal surface, which can protect the metal surface from the corrosive aqueous environment.

4. Conclusions

All the three tested Schiff base DAPs are good corrosion inhibitors for mild steel in 1 M HCl. Among the three DAPs, DAP-1 having methyl substituent exhibited highest inhibition efficiency of 98.58% at 40 mgL⁻¹. DAPs were found to inhibit corrosion by adsorption mechanism which follows Langmuir adsorption isotherm. The formation of a protective film was confirmed by SEM and AFM. PDP study revealed that all three DAPs act as mixed-type corrosion inhibitors. The high value of polarization resistance (*R_p*) obtained from EIS data further confirmed the effectiveness of the studied corrosion inhibitors. The inhibition efficiency (IE) predicted from theoretical data such as, *E*_{HOMO}, *E*_{LUMO}, Δ*E* obtained by DFT approach, was very well-correlated with experimentally obtained IE. The MC simulation results follows the order: DAP-1 > DAP-2 > DAP-3 in both aqueous and gas phases, which is in accordance with the experimental IE. The IE ranking for the studied inhibitors is as follows: DAP-1 > DAP-2 > DAP-3. The highest inhibition efficiency of DAP-1 was attributed to its parallel adsorption on the metal surface.
