IN a recent paper (Harish-Chandra, 1944, referred to as A in this paper) the equations of motion of a point particle interacting with a scalar meson field have been derived. The object of this note is to use these equations to calculate the scattering of scalar mesons by neutrons (or protons) on the classical theory, taking into account the radiation damping. This calculation is entirely similar to the corresponding one, done by Bhabha (1939, 1941) for the case of the vector-mesons. On account of the neglect of the quantum effects and the charge of the meson these calculations are subject to the same limitations as those of Bhabha. Since it is as yet not at all certain whether the actual meson has a spin of 1 or 0 unit, the scattering formulae obtained here are to be looked upon as possible alternatives to those given by Bhabha.

§1. We shall keep to the notation of the previous papers (Bhabha and Harish-Chandra, 1944, Harish-Chandra, 1944). \( \tau \) is the proper time at any point on the world line of the neutron measured from some fixed point on it. \( z_\mu (\tau) \) are the co-ordinates of this point. \( x_\mu \) denote the co-ordinates of any field-point. The fundamental metric tensor is taken to be

\[
\begin{align*}
g_{\mu \nu} = 0 & \quad \mu \neq \nu, \quad g_{00} = -g_{11} = -g_{22} = -g_{33} = 1
\end{align*}
\]

A dot denotes differentiation with respect to \( \tau \) and \( v_\mu = v_\mu (\tau) \) and \( u_\mu = x_\mu - z_\mu (\tau) \).

We shall assume that the neutron has a 'charge' and a 'dipole'. Following Bhabha we consider the scattering due to each of these separately. First we calculate the scattering due to the charge alone.

In the notation of A the equation of motion of the neutron is

\[
m v_\mu - g_1 \frac{d}{d\tau} (U'_{\text{mean}} v_\mu) = -g_1 U'_{\mu \text{mean}}
\]

where \( m \) is the mass and \( g_1 \) the 'charge' of the neutron. \( U'_{\text{mean}} \) and \( U'_{\mu \text{mean}} \) are the modified mean-potential and field respectively. It has been shown in A [Eqs. (3.17) and (3.18)] that

\[
U'_{\text{mean}} = U_{\text{in}} + \bar{U},
\]

\[
U'_{\mu \text{mean}} = U_{\mu \text{in}} - g_1 \left( \frac{1}{6} v_\mu + \frac{1}{2} v_\mu (v) + \frac{1}{2} \chi^2 v_\mu \right) + \bar{U}_\mu
\]
where

\[ \tilde{U} = -g_1 \chi \int_{-\infty}^{\tau} \frac{J_1(\chi u)}{u} \, du, \quad \tilde{U}_\mu = g_1 \chi^2 \int_{-\infty}^{\tau} u_\mu \frac{J_2(\chi u)}{u^2} \, du \]  \hspace{1cm} (2b)

\( U_{in} \) is the ingoing potential and \( U_{\mu\text{in}} = \partial_\mu U_{in} \) is the ingoing field. We assume the ingoing field to be a plane wave travelling in the \( x_1 \)-direction. Assuming that the amplitude of oscillation of the neutron is small compared to the incident wave length we can write

\[ U_{i1} = \gamma \sin \omega_0 t, \quad U_{i2} = 0, \quad U_{i3} = 0 \]  \hspace{1cm} (3)

where \( t = z_0(\tau) \). We assume that the velocity of the neutron is small so that

\[ v_k = \frac{dz_k}{dt} \]

for \( k = 1, 2, 3 \). In conformity with (3) we put (cf. Bhabha, 1939)

\[ z_1 = \frac{\beta}{\omega_0} \sin (\omega_0 t + \delta), \quad z_2 = 0, \quad z_3 = 0 \]

\[ v_1 = \beta \cos (\omega_0 t + \delta), \quad v_1 = -\beta \omega_0 \sin (\omega_0 t + \delta) \]

\[ v_0 = 0, \quad v_2 = v_3 = 0 \]  \hspace{1cm} (4)

We assume the amplitudes \( \beta \) and \( \gamma \) to be small so that quantities quadratic in them may be neglected. Putting \( x_\mu = z_\mu(\tau) \) we get for (2)

\[ u_1 = z_1(\tau) - z_1(\tau') = \frac{\beta}{\omega_0} [\sin (\omega_0 t + \delta) - \sin (\omega_0 t' + \delta)] \]

\[ u_2 = u_3 = 0 \]  \hspace{1cm} (5a)

\[ u \sim \tau - \tau' = u_0 \]  \hspace{1cm} (5b)

From (2b), (4) and (5) we get

\[ \tilde{U} = -g_1 \chi \int_{-\infty}^{\tau} \frac{J_1(\chi u)}{u} \, du \]

\[ = -g_1 \chi \int_{0}^{\infty} \frac{J_1(\chi u)}{u} \, du = -g_1 \chi \]  \hspace{1cm} (6)

\[ \tilde{U}_0 = g_1 \chi^2 \int_{-\infty}^{\tau} u_0 \frac{J_2(\chi u)}{u^2} \, du \]

\[ = g_1 \chi^2 \int_{0}^{\infty} \frac{J_2(\chi u)}{u} \, du = \frac{1}{2} g_1 \chi^2 \]  \hspace{1cm} (7)
On the Scattering of Scalar Mesons

\[ \tilde{U}_1 = g_1 \chi^2 \int_{-\infty}^{\infty} u_1 \frac{J_2(\chi u)}{u^2} du' \]

\[ = g_1 \chi^2 \int_{-\infty}^{\infty} \frac{J_2(\chi u)}{u} u_1 du \]

\[ = \frac{\beta g_1 \chi^2}{\omega_0} \int_{0}^{\infty} \frac{J_2(s)}{s} [\sin \alpha - \sin (\alpha - \nu s)] ds \]  

(8)

where \( s = \chi u \), \( \nu = \frac{\omega_0}{\chi} \) and \( \alpha = \omega_0 t + \delta \). Using the well-known result that

\[ \int_{0}^{\infty} \frac{J_2(s)}{s^2} e^{-is} ds = \begin{cases} \frac{1}{2} [(1 - \nu^2)^{3/2} + i\nu^3 - \frac{1}{2} i\nu] & 0 < \nu < 1 \\ \frac{1}{2} [-i(\nu^2 - 1)^{3/2} + i\nu^3 - \frac{1}{2} i\nu] & \nu > 1 \end{cases} \]  

(9)

we get

\[ \tilde{U}_1 = -\beta g_1 \omega_0^2 (P \cos \alpha + Q \sin \alpha) \]  

(10a)

where

\[ P = \begin{cases} \frac{1}{2} - \frac{1}{2} \nu^2 & 0 < \nu < 1 \\ -\frac{1}{3} (\nu^2 - 1)^{3/2} + \frac{1}{3} - \frac{1}{2\nu^2} & \nu > 1 \end{cases} \]

\[ Q = \begin{cases} \frac{1}{3} (1 - \nu^2)^{3/2} - \frac{1}{3 \nu^3} & 0 < \nu < 1 \\ -\frac{1}{3 \nu^3} & \nu > 1 \end{cases} \]  

(10b)

Substituting the value of the various quantities in (1) and putting \( m + g_1^2 \chi = M \) we get up to terms of the first order in \( \beta \) and \( \gamma \)

\[ -\beta \omega_0 M \sin \alpha = -g_1 \gamma \cos (\alpha - \delta) 
\]

\[ + \beta g_1^2 \omega_0^2 [P \cos \alpha + Q \sin \alpha] 
\]

\[ - \frac{1}{2} g_1^2 \beta \omega_0^2 \cos \alpha + \frac{1}{2} \chi^2 g_1^2 \beta \cos \alpha \]  

(11)

Equating coefficients of \( \sin \alpha \) and \( \cos \alpha \) on both sides of (11) we get

\[ \beta = \frac{\gamma}{g_1 \omega_0 \left[ P' \omega_0^2 + \left( Q \omega_0 + \frac{M^2}{g_1^2} \right)^{1/2} \right]} \]  

(12a)

\[ \cos \delta = \frac{\omega_0 P'}{\left[ P' \omega_0^2 + \left( Q \omega_0 + \frac{M^2}{g_1^2} \right)^{1/2} \right]} \]  

(12b)

where the positive value of the square root is to be taken. \( P' = P - \frac{1}{2} + \frac{1}{2} \nu^2 \)
so that

$$P' = \begin{cases} 
0 & \nu < 1 \\
-\frac{1}{3} \frac{(\nu^2 - 1)^{3/2}}{\nu^3} & \nu > 1
\end{cases}$$  \hspace{1cm} (12c)

It is clear from (12) that the quantity $M + g_1^2 Q \omega_0$ behaves as the effective mass. For very slow oscillations $\omega_0 \ll \chi$ ($\nu \ll 1$) $Q \approx -\frac{1}{2\nu}$

$$M + g_1^2 Q \omega_0 = M - \frac{1}{2} g_1^2 \chi = m + \frac{1}{2} g_1^2 \chi.$$  

Therefore in this case the field contributes a positive mass $\frac{1}{2} g_1^2 \chi$. On the other hand in the vector meson case the field adds a negative mass $-\frac{1}{2} g_1^2 \chi$ for slow oscillations (cf. Bhabha, 1939).

To calculate the scattering we have to calculate the retarded field at a very distant point $x_{\mu} = (X, Y, Z, T)$ lying on the future light cone from the point $\tau$ on the world line.

$$U^{ret}_{(\kappa, \mu)} = \frac{g_1}{\kappa} (\tau) - \chi g_1 \int_{-\infty}^{\tau} \frac{J_1 (\chi u)}{u} \, d\tau'$$

$$= g_1 \int_{-\infty}^{\tau} \frac{J_0 (\chi u)}{u} \frac{d}{d\tau} \left( \frac{1}{\kappa} \right) \, d\tau'$$

$$= g_1 \int_{-\infty}^{\tau} J_0 (\chi u) \left\{ \frac{1}{\kappa^2} - \frac{\kappa'}{\kappa^2} \right\} \, d\tau'$$  \hspace{1cm} (13)

where $\kappa = u^\mu (\tau') \nu_\mu (\tau')$ and $\kappa' = u^\mu (\tau') \nu_\mu (\tau')$. For a very distant point we can neglect the first term $\frac{1}{\kappa^2}$ and write

$$U^{ret} = -g_1 \int_{-\infty}^{T} J_0 (\chi u) \frac{\kappa'}{\kappa^3} \, d\tau' = -g_1 \int_{0}^{\infty} J_0 (\chi u) \frac{\kappa'}{\kappa^3} \, du$$  \hspace{1cm} (14)

Writing $R = \sqrt{X^2 + Y^2 + Z^2}$ we get up to terms of the first order in $\beta$

$$\kappa' = -X \nu_1 = \beta \omega_0 X \sin (\omega_0 t + \delta)$$

$$u^2 = (T - t')^2 - R^2 + \frac{2X\beta}{\omega_0} \sin (\omega_0 t' + \delta)$$

$$\kappa = (T - t') - X \nu_1 = (T - t') - \beta X \cos (\omega_0 t + \delta)$$  \hspace{1cm} (15)

so that in the same approximation

$$\frac{\kappa'}{\kappa^3} = \frac{\beta \omega_0 X \sin (\omega_0 t' + \delta)}{(u^2 + R^2)^{3/2}}$$

$$= \frac{\beta \omega_0 X (a' - \omega_0 \sqrt{u^2 + R^2})}{(u^2 + R^2)^{3/2}}$$  \hspace{1cm} (16)
if we write $\alpha'$ for $\omega_0 T + \delta$. Thus from (14) and (16)

\[
U_{ret} = - g_1 \beta \omega_0 \chi \int_0^\infty J_0 (\chi u) \frac{\sin (\alpha' - \omega_0 \sqrt{u^2 + R^2})}{(u^2 + R^2)^{1/2}} u \, du
\]

\[
= - g_1 \beta \omega_0 \chi \int_0^\infty J_0 (s) \frac{\sin (\alpha' - \nu \sqrt{s^2 + r^2})}{(s^2 + r^2)^{1/2}} s \, ds
\]

(17)

where $s = \chi u$, $r = Rx$ and $\nu = \frac{\omega_0}{\chi}$. On evaluating (17) and retaining only the terms of the lowest order in $\frac{1}{R}$ we find

\[
U_{ret} = \begin{cases}
  g_1 \beta \frac{X}{R} \frac{\sqrt{\chi^2 - \omega_0^2}}{\omega_0} e^{-\frac{R}{\sqrt{\chi^2 - \omega_0^2}}} \sin (\omega_0 T + \delta), \omega_0 < \chi \\
  g_1 \beta \frac{X}{R} \frac{\sqrt{\omega_0^2 - \chi^2}}{\omega_0} \cos (\omega_0 T + \delta - R \sqrt{\omega_0^2 - \chi^2}), \omega_0 > \chi
\end{cases}
\]

(18)

For the case $\omega_0 < \chi$ the potential falls off exponentially with distance and obviously there is no scattering. We therefore consider the case $\omega_0 > \chi$. In this case the incident wave is consistently with (3)

\[
U_{in} = \frac{\gamma}{\sqrt{\omega_0^2 - \chi^2}} \sin (\omega_0 t - \sqrt{\omega_0^2 - \chi^2} x_1).
\]

(19)

The flow of energy per unit area per unit time in the $x_1$ direction as calculated from the energy-momentum tensor

\[
4\pi T_{\mu\nu} = U_{\mu} U_{\nu} - \frac{1}{2} g_{\mu\nu} (U_\rho U^\rho - \chi^2 U^2)
\]

(20)

is

\[
\frac{U_0 U_1}{4\pi} = \frac{\gamma^2 \omega_0}{8\pi \sqrt{\omega_0^2 - \chi^2}}
\]

(21)

where the bar denotes the average over time. Similarly the flow of energy due to (18) in the direction of the radius $R$ across an element of surface subtending a solid angle $d\Omega$ is

\[
g_1^2 \beta^2 \frac{\cos^2 \theta}{8\pi} \left( \frac{\omega_0^2 - \chi^2}{\omega_0^2} \right)^3 d\Omega
\]

(22)

where $\theta$ is the angle between the incident and the scattered wave i.e., $X/R = \cos \theta$. The differential-scattering cross-section in the direction $\theta$ is therefore

\[
g_1^2 \beta^2 \frac{\cos^2 \theta}{\gamma^2} \left( \frac{\omega_0^2 - \chi^2}{\omega_0^2} \right) \, d\Omega
\]

\[
= 1 \left( \frac{\omega_0^2}{\omega_0^2 - \chi^2} \right) + \frac{\omega_0^4}{(\omega_0^2 - \chi^2)^2} \left[ \alpha + \chi - \frac{\chi^2}{3\omega_0^2} \right]
\]

(23)
from (12a) if we put \( \frac{m}{g_1^2} = a \). Integrating over all directions \( \theta \) we find that the total cross-section is

\[
12\pi \frac{1}{(\omega^2 - \chi^2) + \frac{\omega_0^2}{(\omega^2 - \chi^2)^2} \left[ 3a + 3\chi - \frac{\chi^3}{\omega_0^2} \right]} d\Omega
\]  

(24)

For the spin 1 case the scattering of the transverse mesons is given by (Bhabha, 1939)

\[
6\pi \left( 1 + \frac{1}{2} \frac{\chi^2}{\omega_0^2} \right) \left( \frac{1}{\omega_0^2 - \frac{3\chi^4}{4\omega_0^4}} - \frac{1}{4\omega_0^4} \right) + \left( \frac{3}{2} a + \frac{1}{2} \frac{\chi^3}{\omega_0^2} \right)^2
\]

For high energy this is half of (24) independently of the value of \( g_1 \). For \( \chi = 0 \) (24) becomes

\[
\frac{12\pi}{9a^2 + \omega_0^2}
\]

which is of the same form as the corresponding formula of Dirac (1938), \( \text{viz.,} \frac{24\pi}{9a^2 + 4\omega_0^2} \) for the scattering of light by an electron. As found in other cases the cross-section (24) decreases with increasing \( \omega_0 \) as \( \frac{1}{\omega_0^2} \) for high frequencies.

§2. We shall now treat the scattering by the neutron due to the dipole-moment alone. We denote the dipole-vector by \( g_2 S^\alpha \). As already pointed out in A we have to assume

\[
S^\alpha \nu_\alpha = 0
\]

(25)

The equation of rotational motion is [Eqn. (5·36b) of A]

\[
I e_{\mu\nu\rho\sigma} \nu_\nu \tilde{S}^\sigma = g_2 [S_\mu \overline{U}_\nu - S_\nu \overline{U}_\mu]
\]

(26)

where \( \overline{U}_\nu = U_{\nu}' - \nu_\nu \) (\( v^\mu U_{\mu}' \)) \( e_{\mu\nu\rho\sigma} \) is the tensor which is antisymmetric in each pair of indices and \( \epsilon_{0123} = -1 \). Following Bhabha we put \( m \) equal to infinity to simplify the problem. In this case we find from the translational equation that \( \dot{v}_\mu = \ddot{v}_\mu = \ldots = 0 \), so that we can consider the dipole in the rest system. In the usual three-dimensional vector notation (26) can be written as

\[
I \dot{S} = g_2 [S \cdot U']
\]

(27)

where the components of \( S \) and \( U' \) are \( S_k \) and \( U'_k \) \( (k = 1, 2, 3) \) respectively. The bracket denotes the vector product.

Using (25) we find from (3·19) of A that

\[
U'_\mu = U_{\mu}' + g_2 \left( \frac{1}{3} \tilde{S}_\mu + \frac{\chi^2}{2} \tilde{S}_\mu \right) + \tilde{U}_\mu
\]

(28)
On the Scattering of Scalar Mesons

where

$$\tilde{U}_\mu = g_2 \chi^2 \int_{-\infty}^{t} \frac{J_2(\chi u)}{u^2} \, du'$$  \hspace{1cm} (29)$$

Here we have used the fact that $\tau = t$ and $u_1 = u_2 = u_3 = 0$ so that $S^\alpha u_\alpha = 0$. Also

$$u = u_0 = t - t'$$

so that

$$\tilde{U} = g_2 \chi^2 \int_0^{\infty} S(t - u) \frac{J_2(\chi u)}{u^2} \, du.$$  \hspace{1cm} (30)$$

It is to be noted that the right side of (30) is the same as $\frac{1}{2} \tilde{G}$ of Bhabha [1941, Eqn. (68)] if we replace $M$ by $S$ there. (27) can now be written as

$$I \dot{S} = g_2 [S \cdot U^{in}] + \frac{1}{2} g_2^2 [S \cdot \tilde{S}] + \frac{1}{2} g_2^2 \chi^2 [S \cdot \ddot{S} + g_2 [S \cdot \tilde{U}]]$$  \hspace{1cm} (31)$$

This equation is the same as Eqn. (66) of Bhabha (1941) if we replace $H$ by $2 U^{in}$, $M$ by $S$ and $I$ by $2I$ in the latter and put $K = 0$. Thus corresponding to equations (69) and (70) of Bhabha we put

$$U^{in} = \frac{1}{2} H_o \cos \omega_o t = \frac{1}{2} H$$  \hspace{1cm} (32)$$

$$S(t) = S_0 + S_1 \sin \omega_o t + S_2 \sin (\omega_o t + \delta)$$  \hspace{1cm} (33)$$

where $S_0$ is the initial direction of the dipole and $S_0$, $S_1$ and $S_2$ are mutually perpendicular and such that $S_3$ is along $[S_0 \cdot S_1]$. We assume $S_0^2 = 1$. Substituting (32), (33) in (30) and (31) we get corresponding to Eqn. (74) of Bhabha

$$\omega_o S_1 \left[ a \cos \omega_o t + \frac{S_2}{|S_2|} \{ \xi \sin (\omega_o t + \delta) - \zeta \cos (\omega_o t + \delta) \} \right]$$

$$+ \omega_o S_2 \left[ a \cos (\omega_o t + \delta) - \frac{S_1}{|S_1|} \{ \xi \sin \omega_o t - \zeta \cos \omega_o t \} \right]$$

$$= \frac{3}{2g_2^2} [S_0 \cdot H_0] \cos \omega_o t$$  \hspace{1cm} (34)$$

where $a = \frac{3I}{g_2^2}$ and

$$\xi = \begin{cases} 
- \frac{\chi^3}{\omega^6} + \left( \frac{\chi^2 - \omega_o^2}{\omega^2} \right)^{3/2} & \omega_0 < \chi \\
- \frac{\chi^3}{\omega_0} & \omega_0 > \chi \\
0 & \omega_0 < \chi
\end{cases}$$  \hspace{1cm} (35)$$

$$\zeta = \begin{cases} 
\frac{(\omega_o^2 - \chi^2)^{3/2}}{\omega_0} & \omega_0 > \chi \\
0 & \omega_0 < \chi
\end{cases}$$  \hspace{1cm} (36)$$
Here the value of $\alpha$ is twice that used by Bhabha [Eqn. (73) l.c.], while $\xi$ and $\zeta$ are the same as in his case. Since (34) is identical with Eqn. (74) of Bhabha, all the further results derivable from it in terms of $\alpha$, $\xi$, $\zeta$ remain the same. Thus we get

$$\tan \delta = -\frac{\xi}{\zeta} \tag{37a}$$

$$|S_1| = \frac{\alpha}{\sqrt{\xi^2 + \zeta^2}} \tag{37b}$$

$$|S_2| = \frac{3\alpha |H_0| \sin \theta}{2g_2 \omega_0 \left[(\alpha^2 - \xi^2 - \zeta^2)^2 + 4\alpha^2 \xi^2 \right]} \tag{37c}$$

$\theta$ being the angle between $S_0$ and $H_0$. The work done by the external force on the dipole is on the average

$$-\frac{1}{2} g_2 (H \cdot S) = \frac{3}{8} H_0^2 \sin^2 \theta \left(\frac{\alpha^2 + \xi^2 + \zeta^2}{\alpha^2 - \xi^2 - \zeta^2 + 4\alpha^2 \xi^2}\right) \tag{38}$$

To obtain the scattering we have to calculate as before the retarded potential $U^{ret}$ at a very distant point $X, Y, Z, T$ lying on the future light cone from the point $z_\mu (\tau) = (0, 0, 0, \tau)$.

$$U^{ret}_{(x, \mu)} = c_\alpha \left\{ g_2 \int_0^\tau J_0 (\chi u) \left(\frac{S^0}{u} \right) \, d\tau \right\} \tag{39}$$

$$u^2 = (T - t')^2 - R^2 \tag{40a}$$

$$\kappa = T - t' = \sqrt{u^2 + R^2} \tag{40b}$$

Retaining only terms of the lowest order in $\frac{1}{R}$ we get

$$U^{ret} = g_2 c_\alpha \int_0^\infty J_0 (\chi u) \left(\frac{S^0}{u^2 + R^2}\right) \, du$$

$$= -g_2 \text{div} \left\{ \int_0^\infty \frac{\omega_0 J_0 (\chi u)}{u^2 + R^2} \{S_1 \cos (\omega_0 T - \omega_0 \sqrt{u^2 + R^2}) + S_2 \cos (\omega_0 T + \delta - \omega_0 \sqrt{u^2 + R^2})\} \cdot u \, du \right\} \tag{41}$$

where the components of divergence are $\partial_\mu = \left(\frac{\partial}{\partial x}, \frac{\partial}{\partial Y}, \frac{\partial}{\partial Z}\right)$. The term inside the divergence can be evaluated and up to the terms of lowest order in $\frac{1}{R}$ it is equal to

$$\frac{- R \sqrt{\omega_0^2 - \omega_0^2}}{R} [S_1 \sin (\omega_0 T + S_2 \sin (\omega_0 T + \delta))] \text{ for } \omega_0 < \chi$$

$$\frac{1}{R} \left( S_1 \sin (\omega_0 T - R \sqrt{\omega_0^2 - \chi^2}) + S_2 \sin (\omega_0 T + \delta - R \sqrt{\omega_0^2 - \chi^2}) \right) \text{ for } \omega_0 > \chi$$
so that to the same approximation

\[
U^{\text{ret}} = \begin{cases} 
  g_2 \frac{\sqrt{\omega_0^2 - \omega_0^2}}{R} e^{-R \sqrt{\omega_0^2 - \omega_0^2}} \left[ \frac{(R \cdot S_1)}{R} \sin \omega_0 T \right. \\
  \left. + \frac{(R \cdot S_2)}{R} \sin (\omega_0 T + \delta) \right] & \text{for } \omega_0 < \chi \\
  g_2 \frac{\omega_0^2 - \omega_0^2}{R} \left[ \frac{(R \cdot S_1)}{R} \cos (\omega_0 T - R \sqrt{\omega_0^2 - \omega_0^2}) \right. \\
  \left. + \frac{(R \cdot S_2)}{R} \cos (\omega_0 T + \delta - R \sqrt{\omega_0^2 - \omega_0^2}) \right] & \text{for } \omega_0 > \chi
\end{cases}
\]  

(42)

where \( R = (X, Y, Z) \). (42) would agree completely with the expression (84) of Bhabha for \( U^{\text{ret}}_g \) if we replace the scalar products with \( R \) by vector products. When \( \omega_0 < \chi \) there is no radiation. For \( \omega_0 > \chi \) the average rate of radiation in the direction \( R \) inside a solid angle \( d\Omega \) is from (20)

\[
\frac{g_2^2}{8\pi} \frac{(\omega_0^2 - \chi^2)^{3/2}}{\sqrt{\omega_0^2 - \chi^2}} \omega_0 \left[ \frac{(R \cdot S_1)^2}{R^2} + \frac{(R \cdot S_2)^2}{R^2} \right. \\
\left. + 2 \frac{(R \cdot S_1)}{R^2} \frac{(R \cdot S_2)}{R^2} \cos \delta \right] d\Omega
\]  

(43)

corresponding to (84) of Bhabha. The total radiation obtained by integrating (43) over all directions is

\[
\frac{1}{3} g_2^2 (\omega_0^2 - \chi^2)^{3/2} \omega_0 (|S_1|^2 + |S_2|^2)
\]  

(44)

which is the same as (38) due to (37) and (36). The energy flow due to the incident wave (32) is

\[
\left| \frac{|H_0|^2}{32\pi} \right| \frac{\omega_0}{\sqrt{\omega_0^2 - \chi^2}}
\]  

(45)

The total effective cross-section for the scattering of the scalar meson wave is therefore from (45), (44) and (38) and (36)

\[
12\pi \sin^2 \theta \left( \frac{\omega_0^2 - \chi^2}{\omega_0^2} \right)^2 \frac{a^2 + \xi^2 + \zeta^2}{(a^2 - \xi^2 - \zeta^2)^2 + 4a^2 \xi^2}.
\]  

(46)

In terms of \( a, \xi, \zeta \) (46) is the same as Eqn. (82) of Bhabha except for a factor 2. Substituting the value of \( \xi \) and \( \zeta \) the scattering cross-section becomes

\[
12\pi \sin^2 \theta \left( \frac{\omega_0^2 - \chi^2}{\omega_0^2} \right)^2 \frac{a^2 \omega_0^2 + (\omega_0^2 - \chi^2)^2 + \chi^4}{[a^2 \omega_0^2 + (\omega_0^2 - \chi^2)^2 + \chi^4]^2 - 4a^2 \omega_0^2 \chi^2}.
\]  

(47)

Except for a factor 2, (45) agrees entirely with Eqn. (88) of Bhabha in which \( K \) has been put equal to zero. For small \( g_2 \) and not very high frequencies we can expand (47) as a series in ascending powers of \( g_2 \). The first term is

\[
\frac{4\pi}{3} \sin^2 \theta \frac{g_2^4}{I^2} \frac{(\omega_0^2 - \chi^2)^2}{\omega_0^2}
\]  

(48)
which is exactly half of the corresponding expression (86) of Bhabha. Thus for large $\omega_0$ the scattering is double (independently of the value $g_2$) and for small $\omega_0$ half that of transverse vector-mesons. The formulae (47) and (48) have already been discussed by Bhabha in detail.

§3. The above theory will now be compared with the quantum theory of neutral mesons. For simplicity we put $\hbar = 1$. The total Lagrangian for the neutron and the meson fields together is taken to be

$$L = \frac{i}{2} (\psi^+ \beta \gamma^\mu \partial_\mu \psi - \partial_\mu \psi^+ \beta \gamma^\mu \psi) - \mu \psi^+ \beta \psi + g_1 \psi^+ \beta \psi U + g_2 \psi^+ \beta \gamma^\mu \psi \partial_\mu U$$

$$+ \frac{i}{4 \hbar} \psi^+ \beta \gamma^\mu \gamma^\nu \psi \epsilon_{\mu\nu\rho\sigma} \partial^\rho U + \frac{g_1}{4 \hbar} \psi^+ \beta \gamma^\mu \gamma^\nu \gamma^\sigma \gamma^\rho \psi \epsilon_{\mu\nu\rho\sigma} \cdot U$$

$$+ \frac{1}{2} (\partial_\mu U \cdot \partial_\mu U - \chi^2 U^2)$$

(49)

Here $\gamma^\mu$ are the 4-rowed square matrices satisfying

$$\gamma^\mu \gamma^\nu + \gamma^\nu \gamma^\mu = 2g^\mu\nu$$

and $\beta = \gamma^0$. $\psi$ refers to the neutron field and $\psi^+$ is its hermitian conjugate. $\gamma$'s are related to the usual Dirac-matrices $\alpha$ and $\beta$ by

$$\alpha = (a^1, a^2, a^3) = \beta (\gamma^1, \gamma^2, \gamma^3)$$

We assume $\alpha$ and $\beta$ to be Hermitian. $\mu$ is the mass of the neutron. The terms containing $g_1$ and $g_2$ in (49) represent the usual 'scalar' interactions for the charge and the dipole respectively while those containing $g_1'$ and $g_2'$ represent the corresponding 'pseudo-scalar' interactions. Evidently in the classical theory there is no distinction between the scalar and pseudo-scalar interactions since this distinction arises only from the $\gamma$-matrices. To simplify (49) we use the usual representation of $\alpha$ and $\beta$ through two sets of mutually independent Pauli matrices.

$$\alpha = \rho_1 (\sigma^1, \sigma^2, \sigma^3), \beta = \rho_3$$

With this substitution (49) simplifies to

$$L = \frac{i}{2} (\psi^+ \beta \gamma^\mu \partial_\mu \psi - \partial_\mu \psi^+ \beta \gamma^\mu \psi) - \mu \psi^+ \beta \psi + g_1 \psi^+ \beta \psi U$$

$$+ g_2 \psi^+ \left[\alpha U + U_0\right] \psi + g_2' \psi^+ \left[\alpha U + \rho_1 U_0\right] \psi - g_1' \psi^+ \rho_2 \psi \cdot U$$

$$+ \frac{1}{2} (\partial_\mu U \cdot \partial_\mu U - \chi^2 U^2)$$

(50)

where $U = (\partial_1 U, \partial_2 U, \partial_3 U), U_0 = \gamma_0 U$. The Hamiltonian of the system for only one neutron present is found as usual and on ignoring the infinite self-energy of the neutron terms out to be

$$H = (\alpha \cdot p) + \mu \beta - \frac{i}{\sqrt{V}} \Sigma (2k_0)^{-1} (g_1 \rho_3 - g_1' \rho_2) \{a_\alpha e^{i(kx)} - a^*_\alpha e^{-i(kx)}$$

$$+ \frac{1}{\sqrt{V}} \Sigma (2k_0)^{-1} (g_2 \rho_1 + g_2') (\alpha k) - \rho_1 k_0 \{a_\alpha e^{i(kx)} + a^*_\alpha e^{-i(kx)}$$

$$+ 1 \Sigma (N_\alpha + \frac{1}{2})$$

(51)
where \( k_0 = + \sqrt{x^2 + |k|^2} \). \( N_k \) is the number of mesons in the momentum state \( k \) and \( a_k \) and \( a_k^\dagger \) are the corresponding absorption and emission operators respectively.

\[
[a_k, a_k^\dagger] = 1
\]

As usual \( V \) is a large volume in which the field quantities are periodic.

Corresponding to the treatment of §2 we put \( g_1 = g_1' = 0 \) and regard the neutron as an infinitely heavy particle \( (\mu \to \infty) \). A straightforward calculation shows that the scattering due to a pure ‘scalar’ dipole-interaction \( (g_2' = 0) \) is zero in the usual second order \( (g_2) \) approximation. This result holds even when the calculation is performed taking into account the finite mass of the neutron. Also the terms containing both \( g_2 \) and \( g_2' \) vanish for \( \mu \to \infty \), so that in this limit the contribution to the scattering comes purely from the pseudo-scalar interaction. The differential scattering cross-section is thus found to be for \( \mu \to \infty \)

\[
d\sigma = 4 \ d\Omega \left( \frac{g_2'}{\sqrt{4\pi}} \right)^4 \frac{p^4}{E^2} \sin^2 \phi
\]

(52)

where \( p \) is the momentum, \( E \) the energy and \( \phi \) the angle of scattering of the meson. The total cross-section is therefore

\[
\frac{32\pi}{3} \left( \frac{g_2'}{\sqrt{4\pi}} \right)^4 \frac{p^4}{E^2}
\]

(53)

\( \frac{g_2'}{\sqrt{4\pi}} \) is the value of the dipole-moment in the usual units as against its value \( g_2' \) in the ‘Heaviside-units’ which were employed till now. On putting \( I = \frac{\hbar}{2} \) \( (= \frac{1}{2} \) since \( \hbar \) is put equal to 1) and averaging over all \( \theta \), (48) becomes identical with (53) except for a factor 3. This discrepancy is due to the well-known \( (\text{cf. Bhabha, } 1941, \text{footnote on page 340}; \text{also see Bhabha and Madhava Rao, } 1941) \) difference in the classical and the quantum average over the direction of the spin of the neutron. In fact (52) also agrees to the same extent with the corresponding differential cross-section obtained by dividing (43) by (45), expanding in powers of \( g_2 \) and retaining only the lowest term.

I am thankful to Prof. H. J. Bhabha for his criticism and advice.

SUMMARY

The classical formulæ for the scattering of scalar mesons by a neutron are obtained taking account of the radiation damping. The neutron is assumed to possess a ‘charge’ and a ‘dipole moment’. The scattering due to each of these is treated separately. It is found that the formulæ for
the scattering due to the dipole has exactly the same form as the one obtained by Bhabha for the transverse mesons. Due to numerical factors the scattering for large energies of the incident mesons is double, and for small energies half that of transverse vector-mesons.

The scalar and pseudo-scalar charge and dipole interactions are considered in the quantum theory. The scalar dipole interaction does not give rise to any scattering at all, the whole of the scattering being due to the pseudo-scalar interaction. In this case the quantum-theoretical formulæ agree with the corresponding classical ones if the effect of radiation reaction is neglected in the latter.
